MAGIC GENIE

This section provides control of the C1 through F#2 keys. The Full Keyboard, Genie and Music Chord switches cross cancel. The Chord Memory switch is a push-on/push-off type.

FULL KEYBOARD - Up to eight keys may be played on the keyboard with preset voicing.

GENIE - Up to four notes may be played from C1 through F#2. The Genie Volume Control regulates the volume. These notes have a high note priority. The lowest note played also plays the genie bass note. When the rhythm is playing, the genie notes are modulated in the accompaniment pattern and the genie bass alternates between the lowest and highest keys played.

MUSIC CHORD - Pressing a key from C1 through F#2 plays a three-note chord. The organ has the capability of playing major, minor, seventh and minor seventh chords. Because only three notes may be played, the fifth of the chord will not play when a seventh or minor seventh chord is played. The Genie volume control regulates the volume. The chord has a high note priority. When the rhythm is playing the chord is modulated in the accompaniment pattern and the swing bass pattern is played.

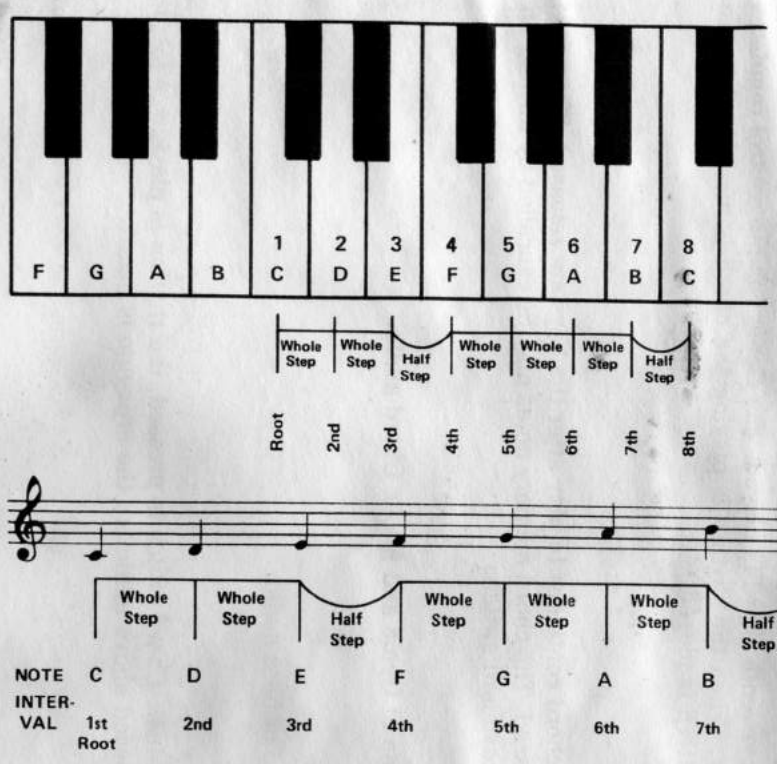
CHORD MEMORY - The genie notes or music chord continues to play after the keys are released. The notes being played are updated each time a key is pressed. The chord memory notes may be cancelled by turning off the chord memory switch or pressing the full keyboard switch.

GENIE VOLUME CONTROL - Regulates volume of Genie and Music Chord audio.

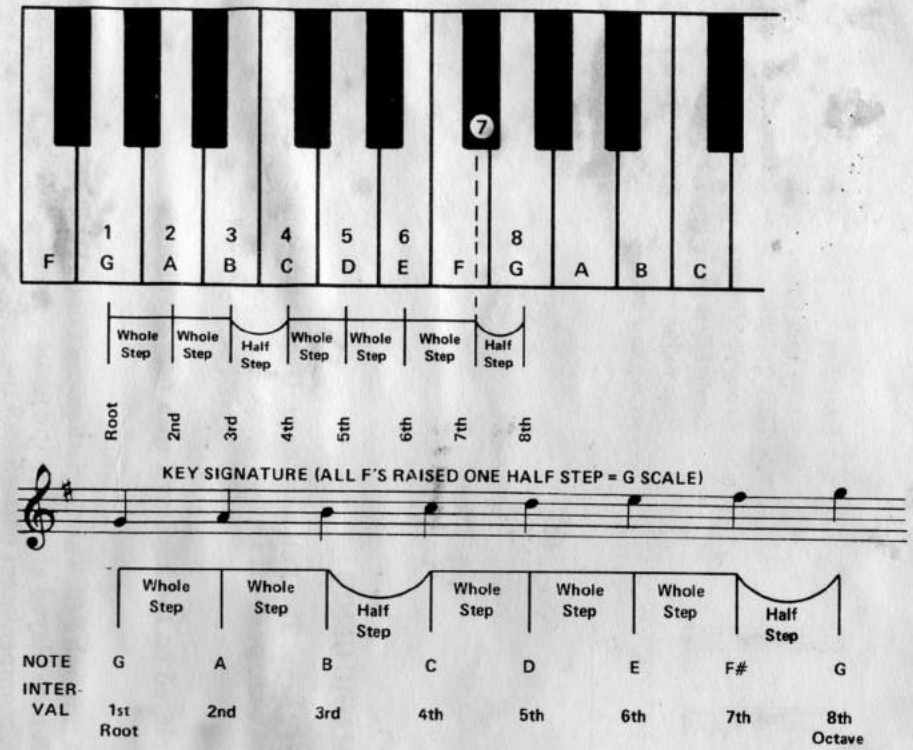
BASS VOLUME CONTROL - Regulates volume of bass audio.

ARPEGGIO VOLUME CONTROL - When the Music Chord switch is pressed, the rhythm is playing, a magic genie chord is playing and this control is increased above minimum the arpeggio is heard.

CHORD RECOGNITION CHART



EXAMPLE OF C MAJOR SCALE



EXAMPLE OF G MAJOR SCALE

MAJOR SCALES – The following procedure will construct any Major Scale.
NOTE: All keys (Black and White) must be counted.

1. The Root or First note of any scale is the key from which the scale is named, (i.e., C scale = C key or G scale = G key).
2. Count 2 physical keys (whole step) to right to arrive at 2nd
   – then –
3. Count 2 physical keys (whole step) to right to arrive at 3rd
   – then –
4. Count 1 physical key (half step) to right to arrive at 4th
   – then –
5. Count 2 physical keys (whole step) to right to arrive at 5th
   – then –
6. Count 2 physical keys (whole step) to right to arrive at 6th
   – then –
7. Count 2 physical keys (whole step) to right to arrive at 7th
   – then –
8. Count 1 physical key (half step) to right to arrive at 8th or octave.

CHORD STRUCTURE – To make chords on any scale

CHORD NAME	STRUCTURE (STANDARD)	PLAYED	
MAJOR	Root 3rd 5th	Root	
MINOR	Root 3rd Lowered One Half Step 5th	Root 3rd Lowered One Half Step	
7TH	Root 3rd 5th 7th Lowered One Half Step	Root 7th Lowered One Half Step (2 keys to left of Root)	
MINOR 7TH	Root 3rd Lowered One Half Step 5th 7th Lowered One Half Step	Root 3rd Lowered One Half Step 7th Lowered One Half Step (2 keys to left of Root)	Note: 5th does not sound

TRACK II RHYTHM

This section controls the rhythm. One of ten rhythms may be played at a time. The rhythm switches cross cancel each other and have a left priority. The start/stop switch is momentary contact. The Auto Start and Track Select switches are push-on push-off.

RHYTHM VOLUME - Controls the volume of the rhythm instruments.

RHYTHM SPEED - Controls the speed of the rhythm pattern.

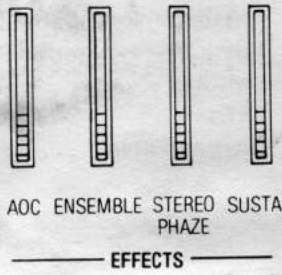
START/STOP - Pressing this switch starts or stops the rhythm.

AUTO START - When this switch is pressed, the rhythm may be started and stopped according to the conditions listed in the table below.

FULL KEYBOARD	GENIE OR MUSIC CHORD	CHORD MEMORY	TO START THE RHYTHM	TO STOP THE RHYTHM
1	0	X	Press any key from C1 through F#2 or press Start/Stop.	Release all C1-F#2 keys then press Start/Stop.
0	1	0	Press any key from C1 through F#2.	Release all C1-F#2 keys.
0	1	1	Press any key from C1 through F#2 or press Start/Stop.	Release all C1-F#2 keys then press Start/Stop or switch off the Chord Memory.

TRACK SELECT - The Light Emitting Diode above this switch is normally on indicating that the top row of rhythms may be selected. When this switch is pressed, the LED switches off and the bottom row of rhythms may be selected.

BEAT - These four light emitting diodes continuously display the rhythm speed. When a rhythm is started, the display resets to the first beat.



AOC — Schematic 1
Ensemble — Schematic 2, 5
Stereophaze — Schematic 2, 5
Sustain — Schematic 2

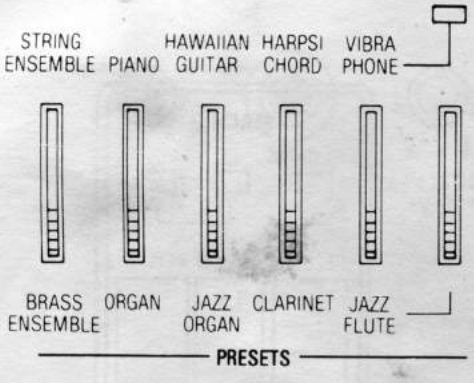
EFFECTS

AOC - Automatic Organ Computer couples the genie notes or music chord to the notes being played with the right hand. The AOC has a range of nine notes. For example, press the Genie switch (Magic Genie section). Then play a C note in the right-hand section and play the C1 through C2 keys in the Magic Genie section. The nine notes C# through A will play along with the C note being played on the right hand.

ENSEMBLE - Adds fast phase modulation to all voices except bass. Has priority over stereo-phaze effect. Adds medium sustain to right-hand presets.

STEREO PHAZE - Adds slow phase modulation to all voices except bass.

SUSTAIN - Adds long sustain to right-hand presets.



Filters — Schematic 4
Effects Switches — Schematic 2

PRESETS

The presets provide the selection of voices for the right-hand keys (G2-C5) and the full keyboard when the Full Keyboard switch (Magic Genie section) has been pressed. These voices are selected one at a time. The preset switches cross cancel each other. The light emitting diode above the Row Select switch is normally on, selecting the top row of presets. When the Row Select switch is pressed, the LED turns off and the bottom row of presets may be selected.

Top Row Presets

STRING ENSEMBLE - 8-foot Sawtooth audio with slow attack, delayed vibrato, ensemble (phase modulation) and medium sustain effects.

PIANO - 8-foot Sawtooth audio with percussive envelope and short sustain (decay) when playing staccato. When playing legato, the decay envelope has medium sustain.

HAWAIIAN GUITAR - 8-foot Sawtooth audio with delayed vibrato and a percussive envelope. Playing staccato results in a short sustain (decay). Playing legato produces a medium sustain (decay).

HARPSICHORD - 8-foot Sawtooth and 16-foot Square Wave audio with a percussive envelope. Playing staccato results in a short sustain (decay). Playing legato produces a medium sustain (decay).

VIBRA PHONE - 16-foot Flute, 4-foot Flute and 2-foot Square Wave audio with a percussive envelope and long sustain. The audio has a tremolo effect.

Bottom Row Presets

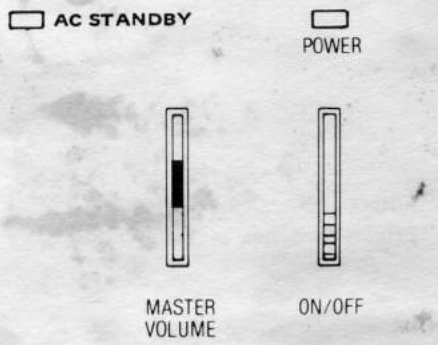
BRASS ENSEMBLE - 8-foot Sawtooth audio with a voltage controlled filter sweep at keydown. The audio has ensemble (phase modulation), delayed vibrato and medium sustain.

ORGAN - A combination of 4-, 8- and 16-foot Flute (triangle wave) audio.

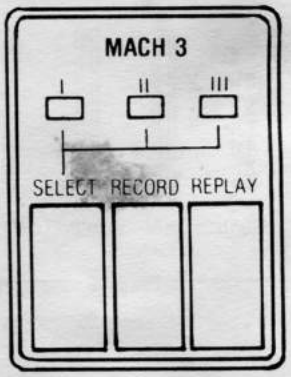
JAZZ ORGAN A combination of 4-, 8- and 16-foot Flute (triangle wave) audio with a short burst of noise at the initial keydown.

CLARINET - 8-foot Square wave audio with slow attack and delayed vibrato.

JAZZ FLUTE - 8-foot Flute audio with delayed tremolo modulation and a percussive attack consisting of 4-foot Flute audio and noise.



—CONTROLS—



Volume Control	– Schematic 5
On/Off	– Schematic 6
AC Standby	– Schematic 6

CONTROLS

AC STANDBY - This light emitting diode is illuminated whenever the organ is connected to a wall outlet regardless of whether the organ is on or off.

MASTER VOLUME - Controls the overall maximum volume of the organ.

ON/OFF - This momentary switch turns the organ on or off. If the organ is turned on but has not been played for over five minutes, it will automatically switch off.

MACH III

This feature permits up to three chord progressions to be pre-recorded then played back automatically.

To program a chord progression:

1. Press the Music Chord switch (and Chord Memory if desired).
2. Select the desired rhythm pattern.
3. Start the rhythm and adjust the rhythm speed control to the desired tempo.
4. Press the Auto Start switch.
5. Press the Record switch. (Record light and one of the three select lights turn on).
6. Press the Select switch until the desired Mach III channel is selected.
7. Play the chord progression.
8. When the chord progression has been recorded, press Start/Stop switch to stop rhythm and recording.

To play back a chord progression:

1. Press Music Chord switch.
2. Press Replay switch (one of the three select lights turns on).
3. Press the Select switch until the desired Mach III channel is selected.
4. Press Start/Stop switch to start or stop the Mach III playback.

Notes:

a. The rhythm may be changed and/or the select switch pressed while the Mach III pattern is being played back.

b. If the replay switch is pressed during playback, the Mach III feature will shut off but the rhythm will continue to play.

c. The C1 through F#2 keys will not sound during Mach III playback. However, Mach III may be auto started from these keys when the Auto Start switch has been pressed prior to starting the rhythm.

Mic Volume — Schematic 4
Mic Input — Schematic 4
Pitch — Schematic 2

LEFT SIDE

MIC VOL - Microphone volume sets the volume of an optional microphone.

MIC IN - Microphone input accepts a standard microphone with 1/4 inch phone plug.

PITCH - Permits the organ to be tuned up to a quarter step sharp or flat. (i.e. C can be tuned to from halfway between B and C to halfway between C and C#.)

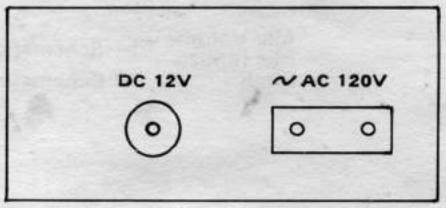
— Schematic 5

RIGHT SIDE

EXP PEDAL - Input for optional expression pedal. The expression pedal range is from minimum volume to the level set by the master volume control.

AUX OUT - Left and right channel outputs to connect organ to an external amplifier or recorder.

HEADPHONE - An output for a stereo headphone. Internal speakers are disabled.



— Schematic 6

REAR PANEL

DC 12V - Connects a car battery (with optional adapter) to organ.

AC 120V - AC line voltage input.

Internal Batteries - A panel on the bottom of the instrument may be removed to permit installation of eight D-cell batteries.

DIMENSIONS

Height — 90mm (3.5 inches)
Width — 860mm (33.875 inches)
Depth — 286mm (11.25 inches)
Weight — 6.8Kg (15 lbs.)

OVERVIEW - The Lowrey V100 is a microprocessor-controlled self-contained portable organ with a forty-nine note keyboard, rhythm, music chord, presets, Mach III accompaniment recorder and two amplifiers to produce a stereo effect.

The microprocessor scans the keyboard, genie switches, rhythm switches and Mach III switches. The keyswitch data are processed into right-hand key and AOC information, left-hand chord and bass information then output to a programmable tone synthesizer.

The programmable tone synthesizer puts out the bass and arpeggio audio plus a combination of up to either eight keyboard notes (full keyboard switch pressed), four genie notes and four right-hand notes (genie switch pressed) or three music chord notes and five right-hand notes (music chord switch pressed). The audio signals are output to the presets filters where they are voiced. The voiced audio may be phase modulated. The audio signal is applied equally to the left and right amplifiers.

The rhythm patterns are stored in read only memory look-up tables. Interrupt pulses are counted until the microprocessor determines that a rhythm beat is to play. A byte of data encoded with rhythm trigger information is output to the rhythm instrumentation causing the appropriate rhythm voices to play.

The Mach III accompaniment stores up to three chord progressions in random access memory. When recalled, the music chord progression will play automatically in a pattern determined by the rhythm style selected. A 47,000 microfarad capacitor provides sufficient voltage and current to permit the random access memory to retain the patterns for up to fourteen days with the organ power turned off.

The three-way power supply can operate from AC line voltage, an external 12 volt DC source (car battery) or internal batteries. When a power source is connected to the instrument, DC voltage is applied to the power switching circuitry. When the on/off switch is pressed, switching transistors apply power to the organ. Not playing the organ for over five minutes will cause the power switching circuitry to switch off power to the organ.

SCHEMATIC 1

CENTRAL PROCESSING SYSTEM

The central processing system consists of four major integrated circuits. These are the microprocessor IC1, the random access memory/input output IC2, a programmable tone synthesizer IC3 and the scan decoder IC4.

IC1 MICROPROCESSOR - This integrated circuit is an 8049 microprocessor. It has an internal 2048 byte read only memory (ROM) and a 128 byte random access memory (RAM). The ROM has been programmed with the sequence of instructions required to obtain the desired outputs and control of the organ based on the input data. The RAM provides temporary storage for data being processed.

IC4 Y-SCAN DECODER - This 1 of 10 decoder is controlled by the microprocessor. The scan decoder and its associated circuits provide the microprocessor with the switch status of the keyboard, rhythm, Magic Genie and Mach III. The x-scan lines are held high by pull-up resistors. The microprocessor selects each y-scan line in turn. The selected y-scan line switches low. If any of the switches connected to that y-scan have been pressed, the corresponding x-scan line is pulled low. The microprocessor inputs the x-scan at port 1. If a change in switch status is detected by the microprocessor it will take the appropriate action to change the keyswitch, rhythm, Magic Chord or Mach III information as required.

IC2 RAM/IO - This integrated circuit contains a 256 byte random access memory (RAM), a programmable timer/counter, two eight-bit input/output (I/O) ports and a six-bit (I/O) port. The RAM is used to store the three magic accompaniment chord (Mach III) progressions. The memory is retained for up to fourteen days when the organ is off due to the extremely slow discharge time of the 47,000 microfarad capacitor at pin 40 of IC2. When the organ is switched off, transistor Q1 cuts off. Voltage from the memory hold capacitor is applied to pin 4 of IC2. This resets all outputs of IC2 to a high impedance state. The amount of current required to retain the RAM content is very small. This gives the 47,000 microfarad capacitor a discharge time of about fourteen days.

The timer/counter counts pulses from the vibrato oscillator. This frequency is input to IC2 at pin 3. The audio amplifier signal is monitored by an audio detector connected to the TØ input of the microprocessor (IC1 pin 1). The microprocessor checks this pin to determine if the organ is being played. As long as the organ is being

played the microprocessor resets the counter within IC2 preventing it from reaching its terminal count. If the organ has not been played for over five consecutive minutes, the counter reaches its terminal count and the timer output (IC2 pin 6) switches low. Transistor Q2 saturates applying a pulse to the power switching trigger circuit which turns off the organ power.

NOTE: If the organ is played at minimum volume, one note at a time, the microprocessor may not recognize a "being played" condition and the organ will shut off when the counter reaches its terminal count.

The I/O ports of IC2 are used as outputs to control the rhythm and Mach III light emitting diodes (LED) and the rhythm, chord and bass trigger pulses.

IC3 PROGRAMMABLE TONE SYNTHESIZER - This integrated circuit generates the bass, arpeggio and up to eight keyboard notes which are split between the Magic Genie Chords and the right-hand melody. The notes are divided as follows:

Full keyboard - up to eight notes may be played with preset voicing.
Genie - four genie notes (left-hand) and four preset notes (right-hand).
Music Chord - three music chord notes (one-finger left-hand) and five preset notes (right-hand).

The master oscillator (Schematic 2) provides a one megahertz clock to IC3. Ten frequency dividers within IC3 are controlled by the microprocessor. When the microprocessor communicates with IC3 a four bit nibble (half a byte) is output from port 1 of the processor to the data inputs (pins 16-19) of IC3. The microprocessor puts out a strobe pulse to latch the data into IC3 then applies clock pulses to IC3 shifting the data into IC3. Data transfer continues in this manner until all the update information is transferred. Each frequency divider divides the two megahertz clock frequency by the programmed value. The pedal and arpeggio audio each pass through a digital to analog converter and an envelope generator and are output to their respective filters. Each of the eight frequency dividers outputs audio signal as 2-, 4-, 8- and 16-foot square waves. Additional circuits combine the square waves into 4-, 8- and 16-foot triangle waves and 8- and 16-foot sawtooth waves. The above mentioned nine waveforms are applied to the upper keyboard (right-hand) digital to analog converter and envelope generator. If the frequency divider is to output lower keyboard (left-hand) audio, the square waves are switched into circuits that provide lower keyboard 4- and 8-foot square waves, an 8-foot triangle and a signal to an internal genie modulator. The lower keyboard signal is applied to a digital to analog converter and an envelope generator. In this organ, only the right-hand outputs, the music chord/genie output, arpeggio and bass outputs are used.

The Music Chord/Genie Keyer Q8 controls the envelope of the music chord/genie audio. When a rhythm is playing pulses are applied to the base of Q8 gating control voltage to IC3.

The voltage applied to pin 13 of IC3 controls the sustain length. As the voltage increases, the sustain length increases.

SCHEMATIC 2
DC CONTROL

The circuits shown on this schematic include the master oscillator, vibrato oscillator, sustain control and percussion decay control.

Q11, Q10 MASTER OSCILLATOR, TUNING DRIVER - The master oscillator frequency is adjusted to provide a center frequency of one megahertz. This frequency is applied to the programmable tone synthesizer IC3 (Schematic 1) where it is divided to provide the audio frequencies for the organ. The tuning driver (Q10) and its emitter capacitor are integral components of the oscillator's tank circuit. The bias voltage applied to the base of Q10 is controlled by the pitch control. As the position of the pitch control changes, it directly affects the bias of Q10 which increases or decreases the capacitance to ground and retunes the oscillator. When vibrato is enabled, a low frequency sine wave modulates the bias voltage via the pitch control creating vibrato (frequency modulation).

IC9D, IC9E, IC10C VIBRATO OSCILLATOR - The vibrato oscillator generates a low frequency of about seven hertz. This frequency is output to several circuits to create tremolo (amplitude modulation), vibrato (frequency modulation), a timer/counter input to IC2 (1-E10) for the automatic shut-off feature and a signal to flash the power LED when a low voltage condition exists.

IC10A, Q13, Q14, IC15A, IC4C - VIBRATO ENABLE - The output of IC10A is normally high. This high level saturates Q13 which in turn saturates Q14 grounding the vibrato/tremolo signal output from the vibrato oscillator circuit. Some of the presets enable the vibrato by applying positive voltage to the input of IC10A. Its output switches low turning off Q13 which turns off Q14 ungrounding the vibrato/tremolo signal. The tremolo signal now passes to the tremolo modulator. The vibrato signal passes through IC15A which is normally turned on and modulates the master oscillator creating vibrato (frequency modulation). When vibraphone is enabled, the output of IC4C switches low grounding the base of Q13 through D14 and switching off IC15A. This enables the vibrato/tremolo output from the vibrato oscillator; however, since IC15A is now off very little of the signal reaches the master oscillator. The net result is that the vibraphone voice has tremolo with a very slight vibrato.

IC10B, IC10E, IC10D, Q12, IC10F - ENVELOPE TRIGGERS - When a key is pressed initially (after all right-hand keys have been released) the any key down output (IC2 pin 2 1-D11) switches high and remains high until all right-hand keys have been released. IC10B inverts this voltage to a low and applies it to the following circuits.

1. Capacitor C36 develops a negative going pulse (hi-low-hi) which momentarily switches the output of IC10E high triggering the slow attack envelope.
2. Capacitor C39 develops a negative going pulse (hi-low-hi) which momentarily switches the output of IC10D high. This triggers the brass filter envelope. The vibrato/tremolo effect is disabled for the length of this pulse creating a delayed vibrato effect for the vibrato presets.
3. A negative going pulse (hi-low-hi) is developed across capacitors C37 and C38. This pulse is inverted through IC10F and applied to the four-foot percussion envelope generator. The pulse width is shortened when the jazz organ preset is enabled and disabled when vibraphone is enabled.

IC9, IC15, Q9, Q15, Q16 SUSTAIN CONTROL - The sustain length is controlled by changing the voltage reference into the programmable tone synthesizer IC3 pin 13 (1-C10). A voltage divider consisting of R67 and R68 establishes a maximum input voltage to IC3 pin 13 of about +2 volts DC. Before any switches are pressed, the voltage at the junction of R67 and R68 is grounded through Q9, the sustain switch, the ensemble switch, Q15 and Q16. Three sustain lengths are available depending on the switches selected.

Short Sustain - when a percussion preset is selected, positive voltage is applied to pin 6 of IC15C. This enables pulses from the percussion sustain decay oscillator to be applied to Q16. The average DC voltage resulting from Q16 alternately switching between cutoff and saturation gives the percussion presets a short sustain.

Medium Sustain - Transistor Q204 is biased on. When Q15 is cut off (brass or string preset on) or the ensemble switch is pressed, the emitter of Q204 switches to +.75 volt DC providing a medium sustain.

Long Sustain - Pressing the sustain switch opens the path to ground in the emitter circuit of Q9 this results in maximum sustain. When vibraphone is selected, the base of Q9 switches low. Q9 cuts off opening the path to ground which results in maximum sustain.

SCHEMATIC 3

RHYTHM INSTRUMENTATION

The rhythm instruments are controlled by the microprocessor (Schematic 1). The frequency of the rhythm clock multivibrator (Schematic 1) is controlled by the rhythm speed control. When a rhythym pattern has been selected and the rhythm has been started, the microprocessor counts pulses from the rhythm clock multivibrator. When a predetermined number of clock pulses have been counted, the microprocessor addresses the rhythm table for the selected rhythm and extracts a byte of data containing the bit pattern of the instruments that are to play at a given time point. This byte of data is transferred to IC2 (Schematic 1) and output through port A (IC2 pins 21-28) to the rhythm instruments.

The outputs of IC2 (Schematic 1) momentarily switch high for the instrument voices that are to play. This voltage is developed into a pulse across a DC isolation capacitor and applied to an instrument generator. Each instrument generator is a tuned filter. A pulse applied to the generator triggers a ringing oscillation that approximates the sound of a drum being struck.

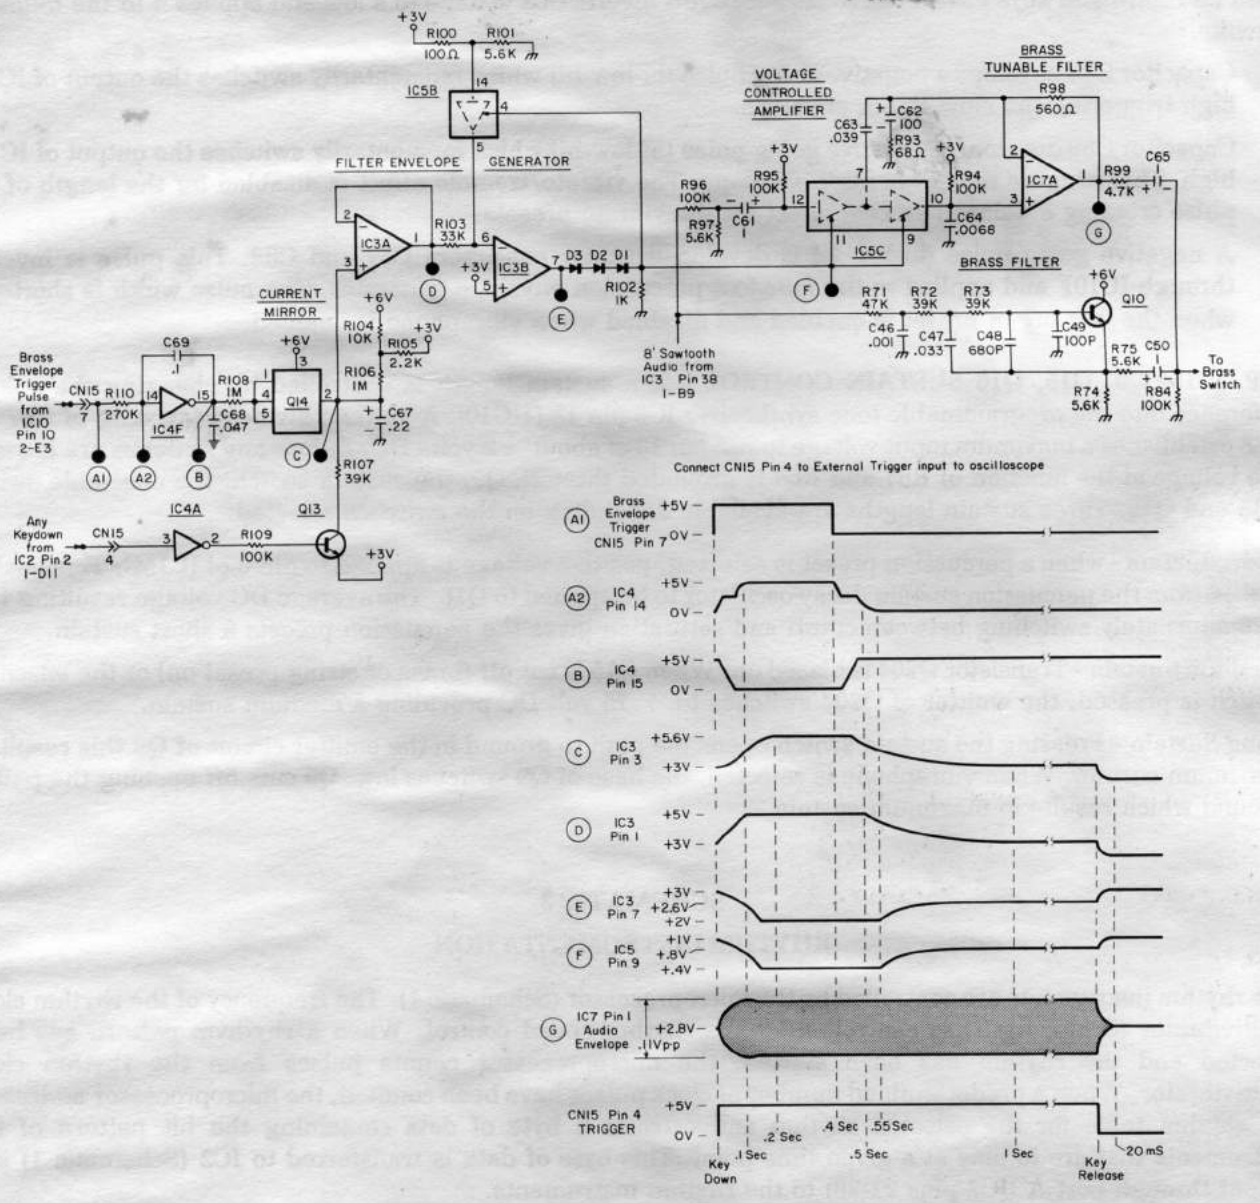
The brush and cymbal are created by first generating DC voltage envelope then applying this voltage to a noise keyer. The burst of noise approximates the sound of a cymbal or a brush striking a snare drum.

All of the rhythm instrument voices are amplified by the rhythm preamp. IC36A is switched on when the rhythm is to play and permits the rhythm audio to pass to the output preamp via the rhythm volume control.

SCHEMATIC 4

QUALITY CONTROL

The high-pass, low-pass and band-pass filters shown on this schematic shape the waveforms output from the programmable tone synthesizer (Schematic 1) to create the tonal characteristics of each instrument. Special effects are used to create the attack and decay characteristics of some of the voices.



BRASS FILTER, ENVELOPE GENERATOR - Initially, Q13 is saturated. This clamps the input voltage to IC3 pin 3 to 3 volts. IC3 "sees" +3 volts as analog ground. The output of IC3 (pin 1) is applied to IC3 pin 6 causing its output (pin 7) to be 3 volts. Diodes D3, D2 and D1 reduce this voltage to about 1 volt which is applied to the control pins of IC5 pin 4, 9 and 11. When a key is pressed, Q13 cuts off. The Envelope Trigger pulse applied to IC4 pin 14 is inverted to a low. Current mirror Q14 "reflects" this as a high causing C67 to charge to +6 volts. The voltage at pin 1 of IC3 follows the charging curve of C67. IC3B inverts the voltage then applies it through D3, D2 and D1 to the control pins of IC5B and IC5C. As the voltage becomes more negative (with respect to the

+3 volt analog ground reference), the amount of signal passing through IC5 increases. This signal mixes with unmodulated brass audio creating the brass voice.

SLOW ATTACK - The clarinet and string ensemble have a slow attack effect. The position of the string ensemble switch determines if 8-foot square wave audio (string off) or 8-foot sawtooth audio (string on) is to be applied to the clarinet/string slow attack modulator. IC6B "sees" +3 volts as an analog ground. When a key is pressed, IC5A switches on bypassing R56 and "grounding" the audio signal across C40. When IC5A switches off at the conclusion of the keydown pulse, R56 is switched in series with C40 raising the input above "ground". The input reference changes by the time constant of R56 and C40 developing the slow attack effect.

PERCUSSION ENVELOPE GENERATOR - The jazz organ and jazz flute use a short burst of noise and 4-foot flute audio as part of the characteristic of that voice. IC6A "sees" +3 volts as analog ground. IC5A is normally on "grounding" the audio input to IC6A through C89. When a key is pressed, IC5A momentarily switches off permitting a short burst of noise and four foot flute to pass to IC6A.

SCHEMATIC 5

CHORUS MODULATOR AND AMPLIFIER

The audio signals that have been enabled are applied equally to the left and right channel output preamps. If the ensemble or stereophaze switch is pressed, chorus modulated audio is applied to both output preamps. Two voltage controlled amplifiers (VCA) are contained within IC31. The voltage output from IC31 pin 2 varies from +12.8V (min) to +13V (max). Pin 1 is a current input. As the volume increases, the emitter voltage decreases from +4V to zero (max) reducing the control current which increases the volume. The audio output from the VCA is applied to the power amplifier which amplifies the signal to drive the speakers.

CHORUS MODULATOR - The chorus modulator consists of an analog shift register (IC15), a high frequency voltage controlled oscillator and a low frequency oscillator. The audio signal output from the audio collector amp (IC13A) is applied to the analog shift register. The audio signal is sampled and shifted through the 512 stage shift register at the rate of the voltage controlled oscillator (VCO). The signal that appears at the output of the shift register is a composite of the audio signal samples superimposed on the high frequency clock. The low pass filter Q27 removes the high frequency clock component and enables the audio signal to be applied to IC13 pin 6. IC13B performs two functions. When the ensemble, stereo phase, brass and string switches are off, IC10C is enabled. This connects the output of IC13B to its inverting input. The gain of an op-amp is determined by the value of the feedback resistor divided by the input resistor. Since IC10C represents a short circuit (zero ohms), there is no gain and as a result no output from IC13B. IC10C switches off when the ensemble, stereophase, brass or string switch is pressed. Resistor R233 provides the feedback resistance. The op-amp has unity gain (R233=R231), inverts the audio and applies it to the output preamps.

The triangle shaped waveform output from the low frequency oscillator causes the speed of the high frequency oscillator to increase and decrease. This varies the time delay required for the sampled audio signal to move through the shift register. The phase shift between the modulated audio and the unmodulated audio creates the chorus effect.

Q301, Q303 VOLUME REGULATOR, MUTE SWITCH - At power turn on, the capacitor at the base of mute switch Q303 appears as ground. Q303 saturates connecting IC31 pin 2 to pin 1 keeping the volume at minimum. Once the capacitor has charged, Q303 cuts off and normal control of the volume is restored. The overall volume of the organ is controlled by the volume control. Positive voltage is output from IC31 pin 2 and applied through the volume control to the base of Q301. As the volume control is moved from minimum to maximum volume, the emitter voltage of Q301 decreases from +4V to zero. The control current input to pin 1 decreases and the overall volume increases. The optional expression pedal permits control of the volume between minimum and the level set by the volume control.

IC32 POWER AMPLIFIER - Two power amplifiers are built into this integrated circuit. Each channel handles about five watts of power. The amplified signal is applied to the speakers through contacts of the headphone jack.

Q302 SIGNAL DETECTOR - When the organ is played, right channel audio signal is applied to the base of Q302. The audio is inverted and applied to the test zero (TØ) input to the microprocessor (see Schematic 1). The microprocessor checks this pin during normal operation. As long as the organ is played, it resets the timer within IC2 (Schematic 1). When the organ is not played, the timer is not reset. It reaches its terminal count after about five minutes then puts out a negative going pulse which turns the organ off.

SCHEMATIC 6

POWER SUPPLY

This instrument can operate on voltage from any of three sources. Eight D cells may be installed in the organ to provide power. An external twelve volt DC source (car battery) may be used or standard AC line voltage may be used to provide power for the instrument. The AC voltage is stepped down across the transformer then rectified into DC across the full wave bridge. Note that the "AC Standby" LED will be on whenever the organ is connected to AC. Transistor Q601 is a ripple filter to remove any AC or DC ripple that may be present. Diode D601 provides DC protection to the instrument. If the external DC power source is connected with reverse polarity D601 would be reverse biased preventing any current flow.

DC voltage is always applied to the power switching circuits (IC41, IC42) regardless of whether or not the organ is turned on. It is recommended that internal batteries be removed if the instrument will not be played for an extended period of time to conserve battery life.

POWER ON/OFF SWITCHING [INITIAL CONDITIONS] - When power is first connected to the instrument, IC41D pin 12 appears as a high and IC41D pin 13 appears as a low. Pin 11 of IC41D is high which resets IC42A and IC42B (Q outputs reset low, Q-bar outputs reset high). Once C401 charges, both inputs to IC41D are high and its output switches low. The low level output from IC42B keeps Q411 cut off. Q411 in turn keeps power enable switcher Q404 cut off which keeps Q403 cut off. This prevents the +14 volt supply from reaching any of the organ's circuits. The Q-bar output of IC42A is high. This high level causes Q402 to saturate resetting the microprocessor. The voltage output from IC42A is applied through R413 to C405. Once the capacitor charges sufficiently, the set input to IC42 (pin 6) switches high. This switches the Q-bar output low. C405 discharges through R413 to the low level at the Q-bar output of IC42A.

POWER TURN ON - When the power on/off switch is pressed, positive voltage is applied to C403. As this capacitor charges, pin 1 of IC41A becomes more positive. When the voltage at pin 1 exceeds the threshold, pin 3 of IC41A switches low (both inputs are high) causing pin 4 of IC41B to switch high. The low to high transition clocks IC42A and B. The Q output of IC42B switches high. Q411 saturates which causes Q404 to saturate causing Q403 to saturate. This supplies +14 volts to the instrument. The Q-bar output of IC42 momentarily switches high causing Q402 to saturate which resets the microprocessor. The high level output from IC41B is applied to pin 1 of IC41A. Pin 4 of IC41B will remain high as long as the power switch continues to be pressed. Once the power switch has been released, C403 begins to discharge. As the voltage drops below the threshold of IC41A pin 1, pin 3 switches high and pin 4 of IC41B returns to a low. This delay prevents the instrument from being turned on and off rapidly.

POWER TURN OFF - When the power on/off switch is pressed, the same sequence occurs as for power turn on. The only difference is that when IC42B is clocked, its output switches to a low causing the power enable switchers to cut off.

AUTOMATIC SHUT OFF - When the organ has not been played for more than five minutes, pin 6 of IC41B switches low causing pin 4 to switch high. The low to high transition clocks IC42B switching its output low cutting off the power enable switchers.

Q405, IC41C LOW VOLTAGE DETECTOR, SHUT OFF TRIGGER - Transistor Q405 is normally saturated keeping IC41C pin 8 low which holds pin 10 high. If the regulated six volt supply decreases (i.e. weak batteries) below about four volts, Q405 begins to cut off. As the transistor approaches cutoff, its collector becomes more positive. When the voltage at pin 8 reaches the threshold, pin 10 switches low. A pulse is developed across C406 momentarily switching pin 12 of IC41D low. Pin 11 of IC41D puts out a positive pulse which resets IC42A and IC42B to their off conditions, shutting off the organ.

+6 VOLT REGULATOR - Q408, Q409, Q410 and D406 work together to regulate the +6 volt supply. As long as the voltage at the collectors of Q408 and Q409 is six volts or greater, the output will be six volts.

Q406, Q407 POWER INDICATOR, LOW VOLTAGE FLASHER - When the supply voltage is greater than about nine volts, Q406 is saturated, lighting the power indicator LED. If the supply voltage drops below nine volts, Q406 begins to cut off. Q407 has pulses from the vibrato oscillator applied to its base. As Q406 begins to cut off, Q407 begins to take control of the LED causing it to flash off and on providing a low voltage warning. If the supply voltage drops below four volts, the organ automatically shuts off.

Adjustments have been made prior to shipping from the factory. An adjustment may be required after repairs have been made to a defective circuit where the adjustable component is located. All adjustment components are accessible through access holes in the printed circuit boards. All controls are at minimum and switches are off except as noted in the following procedures.

SCHEMATIC 2

L1 MASTER OSCILLATOR TUNING PROCEDURE

1. Press the organ preset switch (to disable vibrato).
2. Place the pitch control to midpoint (detent position).
3. Connect an oscilloscope to IC9 pin 6.
4. Insert a plastic tuning wand into the core of L1.
5. Adjust L1 until the oscilloscope displays a 1MHz waveform (1 microsecond (uS) period). (See waveforms.)

Alternate Method:

1. Press the organ preset switch (to disable vibrato).
2. Press the Genie switch and chord memory switch.
3. Increase the Genie Volume control to maximum.
4. Press the A1 key.
5. Adjust L1 to zero beat the A1 key with an A-220 tuning fork (or other frequency standard).

R87 KEYDOWN PULSEWIDTH ADJUSTMENT

1. Press the organ preset switch.
2. Connect oscilloscope to IC10 pin 15 (CN15-5).
3. Adjust R87 to obtain a 50 milisecond pulse at keydown.
   NOTE: When Jazz Organ is enabled, the pulse width is reduced to about 4 miliseconds.

SCHEMATIC 4

R209 OUTPUT LEVEL ADJUSTMENT

1. Press the organ preset switch.
2. Press the Genie switch and increase the Genie volume to maximum.
3. Connect oscilloscope (input coupling AC) to IC13 pin 1.
4. Press and hold the C1 key.
5. Adjust R209 for a signal amplitude of .2 volts peak to peak.

R57, R62 SLOW ATTACK ADJUSTMENT

1. Press the clarinet preset switch.
2. Connect an oscilloscope (input coupling AC) to IC13 pin 1.
3. Press and hold the C5 key.
4. Adjust R57 for maximum peak to peak amplitude.
5. Turn R57 until the signal amplitude just begins to decrease.
6. Measure the voltage at the wiper of R57 with a DC voltmeter.
7. Adjust R57 to increase the voltmeter reading by .5 volt DC.
8. Repeatedly press and release the C5 key and adjust R62 to obtain a keydown slow attack envelope of between 40 miliseconds and 60 miliseconds (50mS nominal). See waveform diagams.

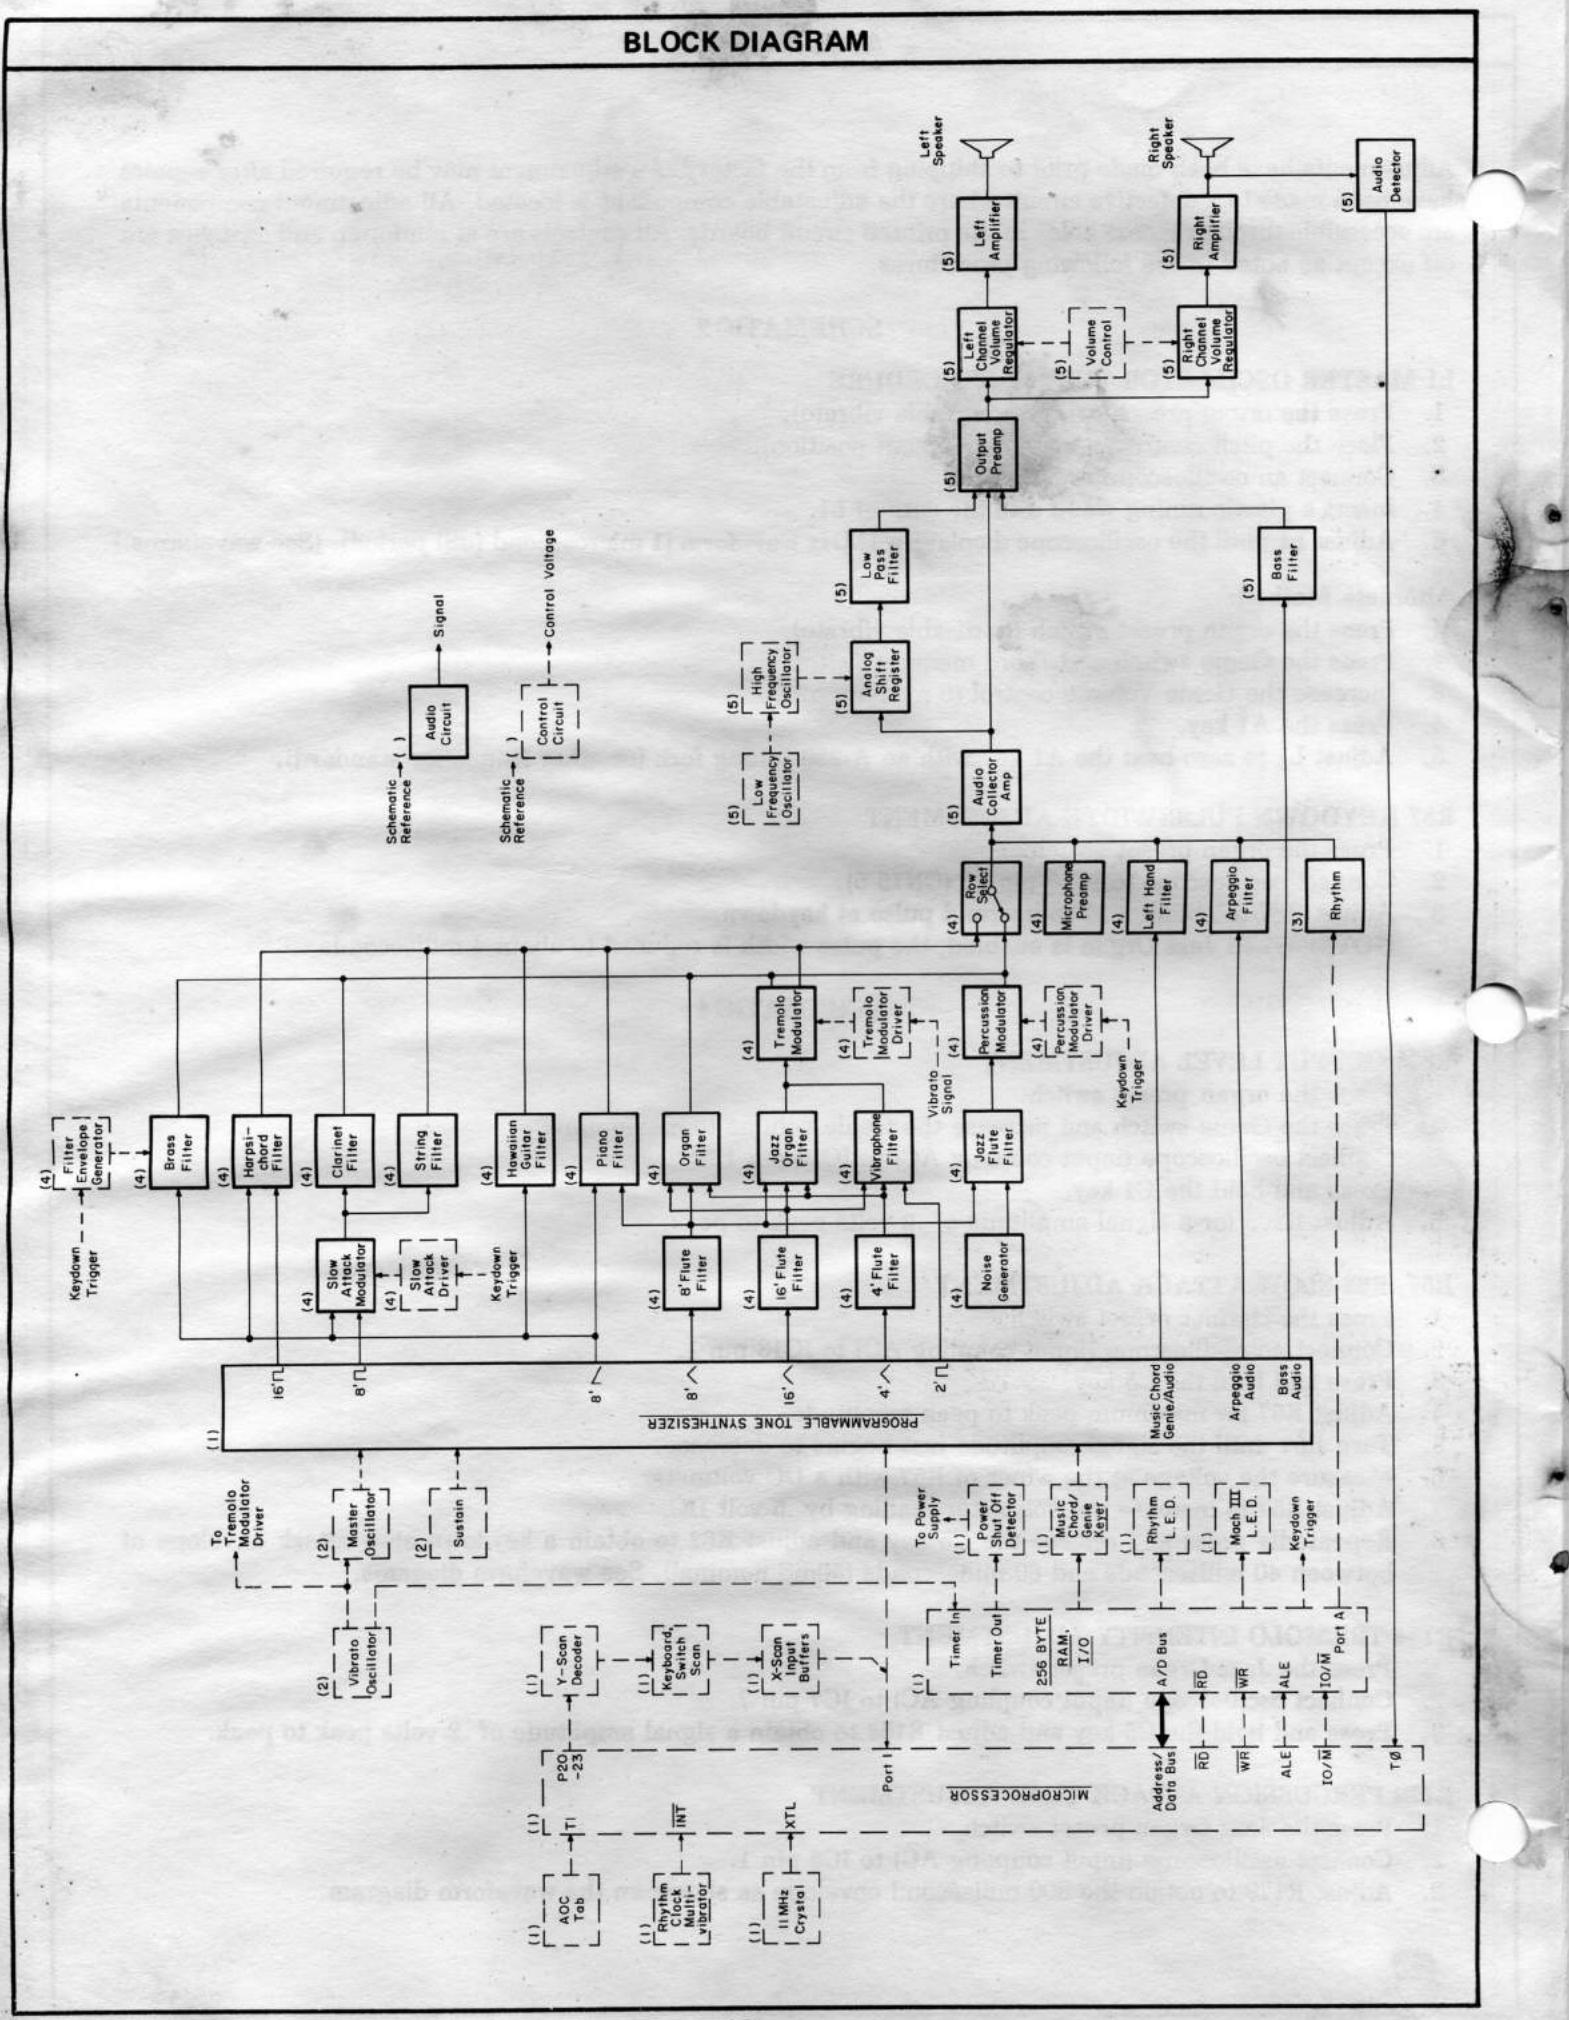
R154 TREMOLO INTENSITY ADJUSTMENT

1. Press the Jazz Organ preset switch.
2. Connect oscilloscope (input coupling AC) to IC7 pin 7.
3. Press and hold the C5 key and adjust R154 to obtain a signal amplitude of .2 volts peak to peak.

R179 PERCUSSION ATTACK TIME ADJUSTMENT

1. Press the Jazz Organ preset switch.
2. Connect oscilloscope (input coupling AC) to IC6 pin 1.
3. Adjust R179 to obtain the 300 milisecond envelope as shown on the waveform diagram.

BLOCK DIAGRAM



SCHEMATIC DRAWINGS, PRINTED WIRING BOARDS

1) The numbering on each printed wiring board begins with Q1, IC1 and D1.
2) Board locations are clearly shown in large letters.
3) Two or more components with the same reference number may be drawn on the same schematic.
4) When components from two or more printed wiring boards are drawn on the same schematic, shaded areas will separate the components and their location will be clearly identified.
5) "S" numbers refer to socket numbers which are screened on PC boards. Pins in sockets are numbered from left to right or bottom to top as board is viewed in organ.
6) All tabswitches, pushbutton switches and keyswitches are shown "off" unless otherwise specified.

TEST EQUIPMENT

1) All voltages are measured to ground reference.
2) Oscilloscope waveforms are approximations.
3) Unless specified, measurements are made with keyswitches, tabswitches and pushbutton switches in the "off" position and controls at minimum.

NOTE: Actual voltages and waveshapes will vary depending on the accuracy of your test equipment, loading, component tolerances, power supply voltages and other variables.

COMPONENTS

1) Resistors have 5 or 10% tolerances and are rated at 1/4 or 1/2 watt unless otherwise specified.
2) Capacitor values are in microfarads (uf) unless otherwise specified.
3) All components are located on indicated boards unless specified.
4) See Parts List for component part numbers.
5) ✠ Denotes factory-tailored component.
6) Resistors with "R" numbers and capacitors with "C" numbers are located in networks or listed in charts as indicated on individual drawings.

OSCILLOSCOPE USAGE

An oscilloscope provides a visual image of events which occur too rapidly to be measured with a voltmeter. When properly used, the oscilloscope becomes a valuable aid in troubleshooting electronic organs.

INPUT COUPLING

The input coupling on most oscilloscopes can be switched between direct (DC) or decoupled (AC).

Direct Coupling [DC]

1. The probe is connected directly to the input of the oscilloscope.
2. Once a zero reference is established, positive and negative voltage measurements can be made.
3. Unless otherwise specified, all waveforms shown on the schematics are made using direct coupling.

Decoupled [AC]

1. A capacitor is placed in series with the probe to block any DC voltage which may be present in the AC signal.
2. The image on the oscilloscope will deflect above and below the established zero reference.

Input - DC
Vertical - 5 Volts per Division
Trigger - Auto

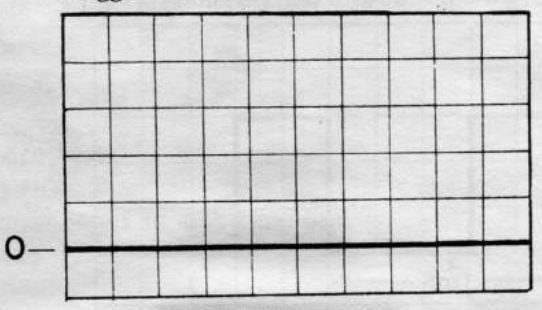

Fig. 6A - Establish Zero Reference

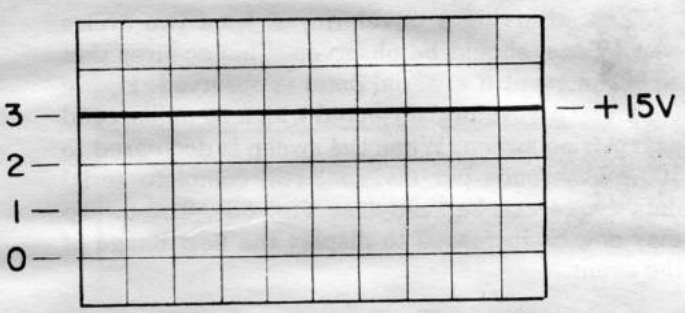

Fig. 6B - Three Division Deflection

CALIBRATION

Any oscilloscope may be calibrated as follows:

1. Set vertical deflection to 5 volts/division (or similar range).
2. Ground the input to the oscilloscope.
3. Align the trace with a horizontal graticule (see Fig. 6A).
4. Unground the input to the oscilloscope, trace should not move.
5. Connect oscilloscope input to a known DC voltage source (i.e. +15 volts).
6. Trace should deflect three divisions in a vertical direction [3 division x 5 volts = 15 volts]. (See Fig. 6B.)
7. Adjust calibration control to obtain a three division (15 volt) deflection.
8. Oscilloscope is now calibrated.

NOTE: If a ten-to-one (or other) attenuator probe is used, the vertical deflection should be multiplied by ten (or other). For example: With a ten-to-one probe, the vertical deflection would have to be set to .5 volts per division to obtain a three division deflection when measuring a 15 volt source.

.5V x 3 Div. = 1.5V 1.5V x 10 atten. = 15V

TIME BASE

Most oscilloscopes have a horizontal time base which controls the movement (sweep) of the trace across the screen from a few seconds to several microseconds.

Frequency and time are inverse functions. As frequency increases, time decreases. The mathematical formula for determining the frequency of a waveform is $F = \frac{1}{t}$ where frequency (F) is in cycles and time (t) is in seconds.

To determine the frequency of a waveform:

1) Determine the time it takes for the waveform to complete one cycle.
2) In Figure 7, a cycle of the waveform takes five divisions. The sweep is set for 200 microseconds per division. The time required for a single cycle is 200uS x 5 divisions or 1000 microseconds = 1 millisecond = .001 second.
3) Using the formula $F = \frac{1}{t}$, the frequency of the waveform is:

$$F = \frac{1}{.001}$$

$$F = 1000\text{Hz}$$

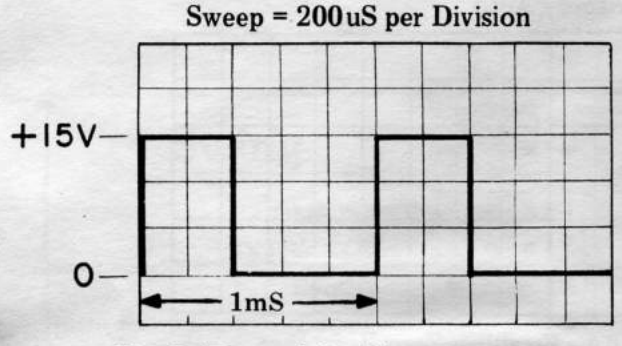

Fig. 7 - Determining Frequency

When observing a waveform, at least two cycles (repetitions) should be observed. This ensures that all of the event (i.e. serial data) is observed. Figure 8A shows a waveform observed with a 20 millisecond per division sweep. When the sweep is decreased to 100 milliseconds per division, two complete serial data cycles can be seen (see Fig. 8B). The sweep may now be increased to display the best image of the event.

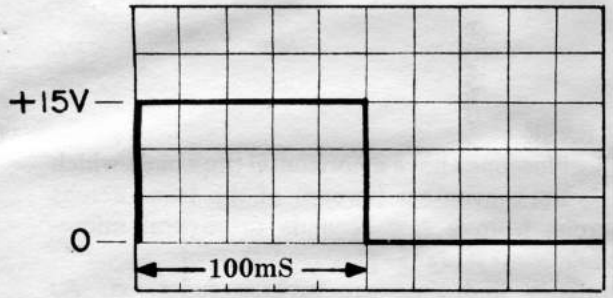

Fig. 8A - Serial data observed with 20mS per Division sweep

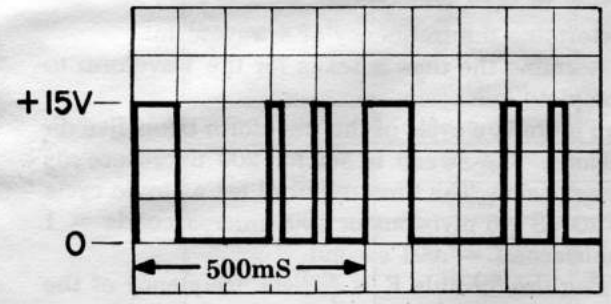

Fig. 8B - Serial data observed with 100mS per Division sweep

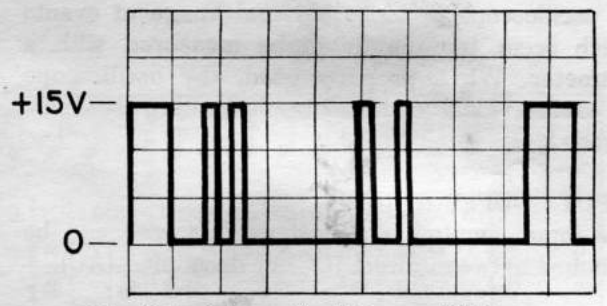

Fig. 9A - Internally Triggered Data

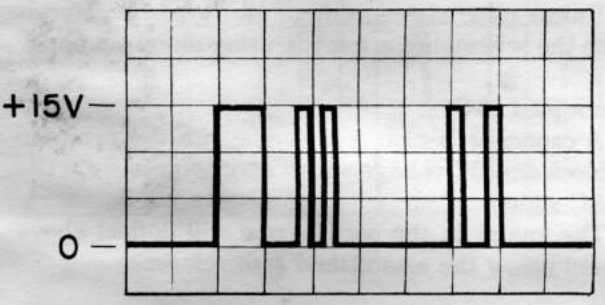

Fig. 9B - Externally Triggered Data

TRIGGERING

Some oscilloscopes have triggered sweep. There are two common types of triggered sweep. Internal triggering relies on the positive or negative going edge of the waveform to start the sweep. The trigger level is controlled by a potentiometer which will cause the sweep to start at the selected voltage level. External triggering is most useful for observing events which occur in a specific relationship to time. Serial data from the Chord Function Generator or Flute Encoder would be an example. Figure 9A shows data being triggered internally. As data bits are added or subtracted from the serial data stream, the image on the oscilloscope will shift dependent on the first data bit (farthest left) used for triggering. The pattern in Figure 9B is externally triggered using the positive edge of the T1 time frame. As data bits are added or subtracted, they will always appear in the same position with respect to the triggering source.

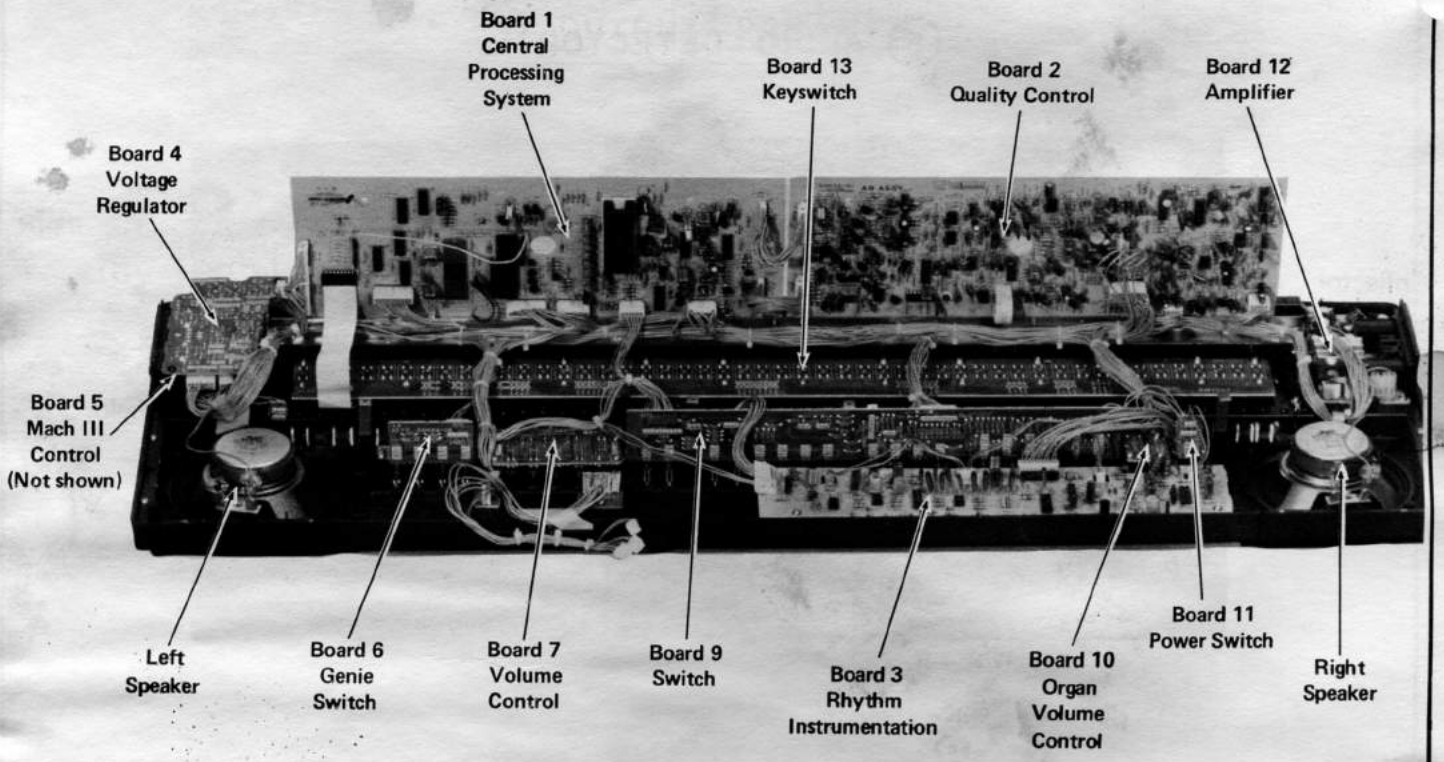
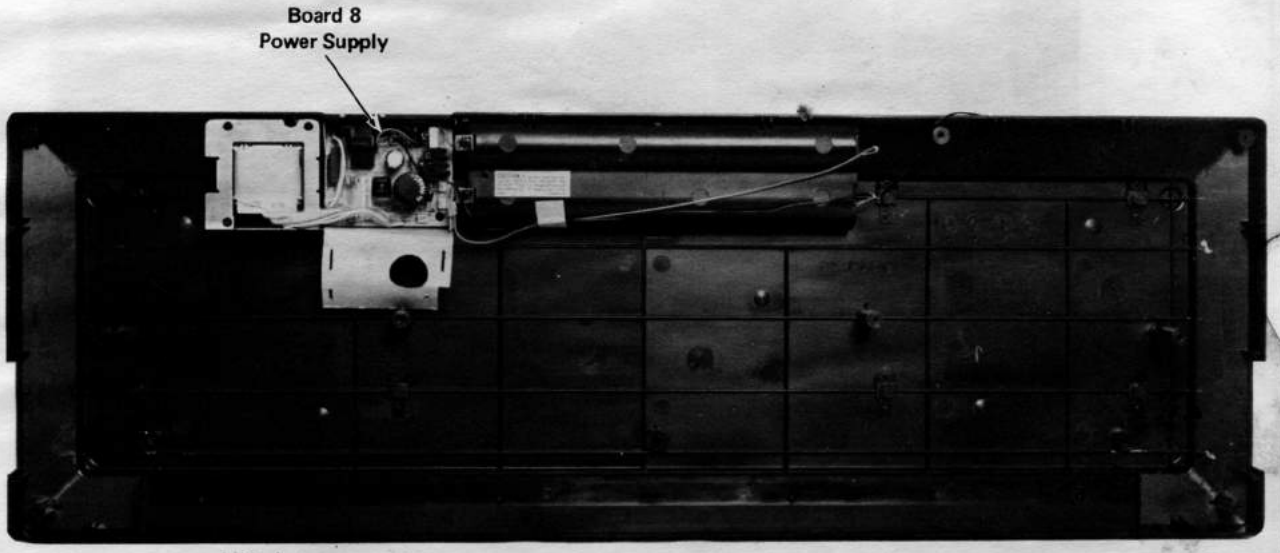
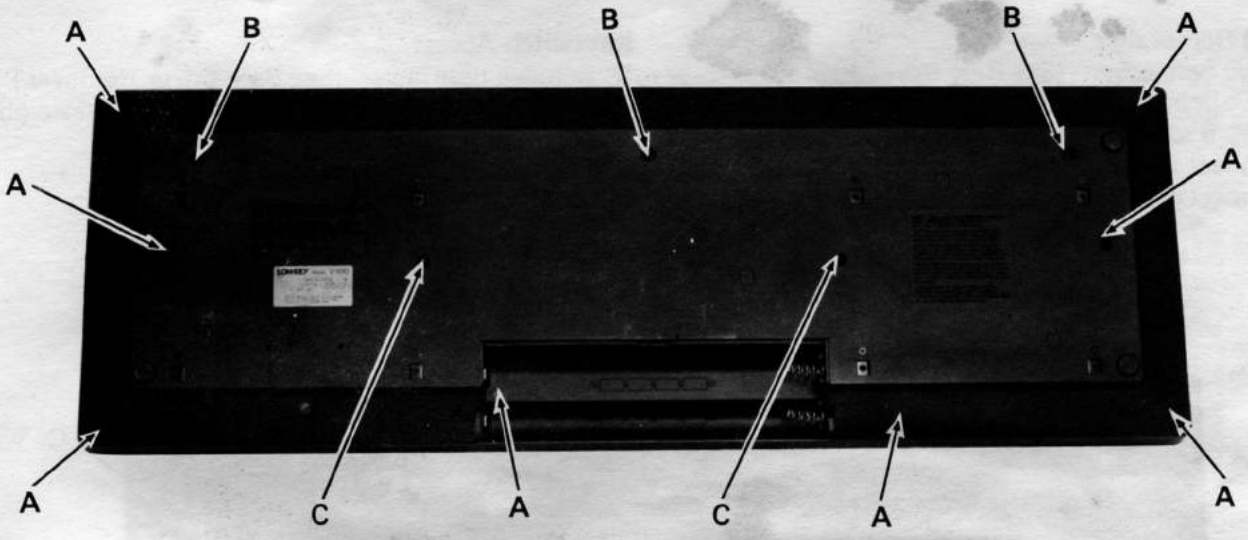
BOARD LOCATION

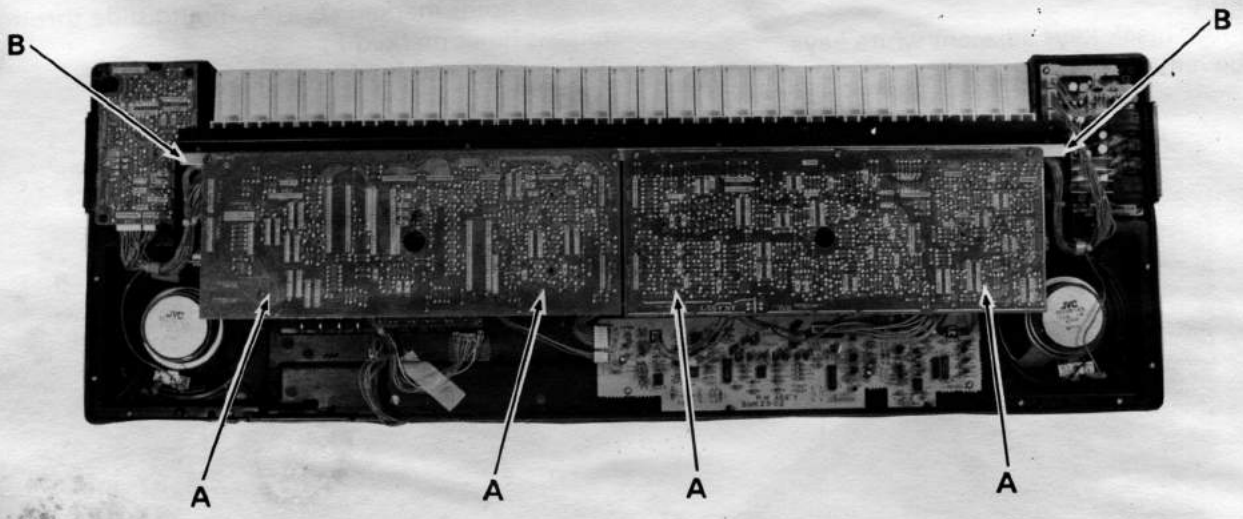






Base Cover Removal

1. Remove 8 screws (plastic tapping) marked A.
2. Remove 3 screws (steel tapping with washers) marked B.
3. Remove 2 screws (steel tapping) marked C.
4. Lift base cover from unit carefully so that power supply cables are not damaged.



Board Panel Disassembly

1. Remove base cover. (See Base Cover Removal.)
2. Remove 4 screws marked A.
3. Board panel will now raise and fold back into service position.
4. Remove 2 screws marked B at ends of board panel bracket.

Keyboard Removal

1. Remove base cover. (See Base Cover Removal.)
2. Remove board panel. (See Board Panel Disassembly.)
3. Remove 6 screws marked A.
4. Disconnect Q408 by removing screw marked B.
5. Disconnect ground wire by removing screw marked C.

Keyswitch Access

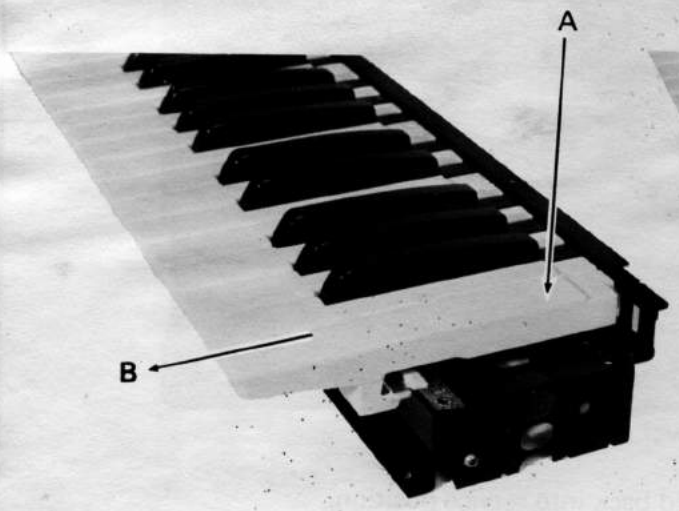
1. Remove base cover. (See Base Cover Removal.)
2. Remove board panel. (See Board Panel Disassembly.)
3. Disconnect ribbon cable.
4. Remove all 25 screws (with spacers).

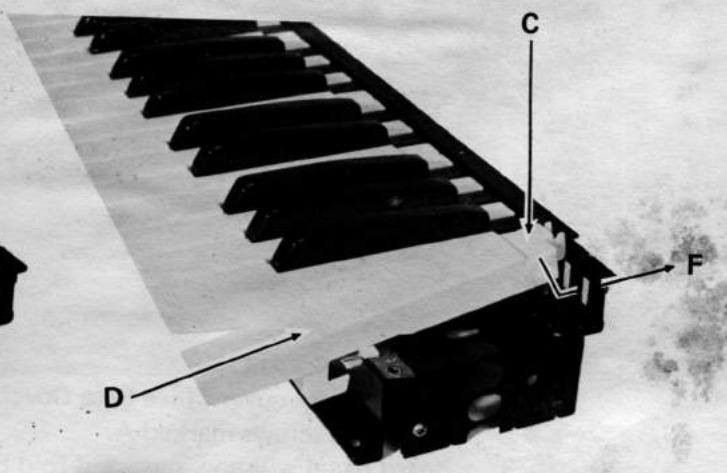
Key Removal

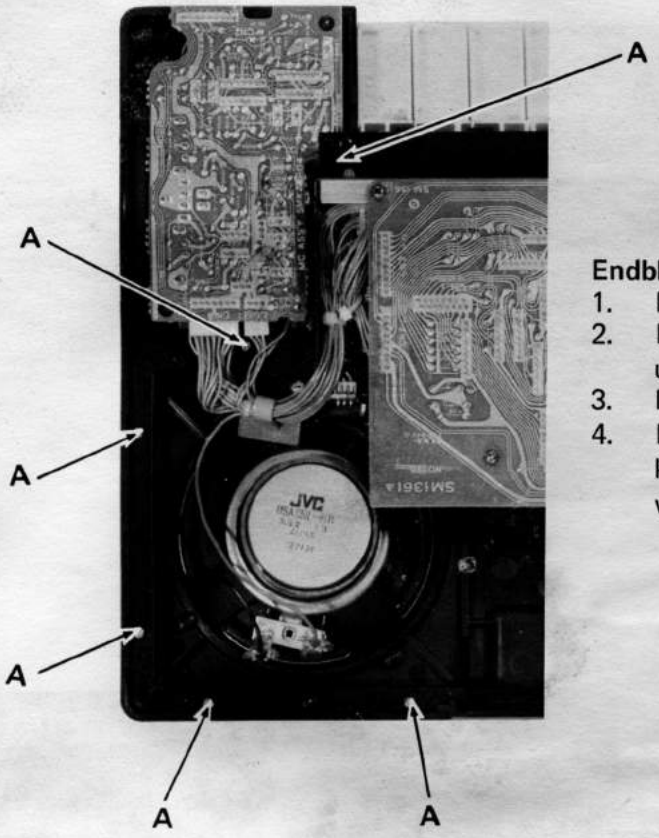
1. Remove keyboard assembly. (See Keyswitch Access.)
2. Depress key at point A and pull in direction of point B.
3. To remove black keys adjacent white keys must be removed first.

Key Installation

1. Insert key over key guide allowing the compression spring to rest on the boss.
2. Depress key at point marked C and push in direction of point marked D. Key should slide through chassis holes marked F.
3. Release key and it will snap into position.





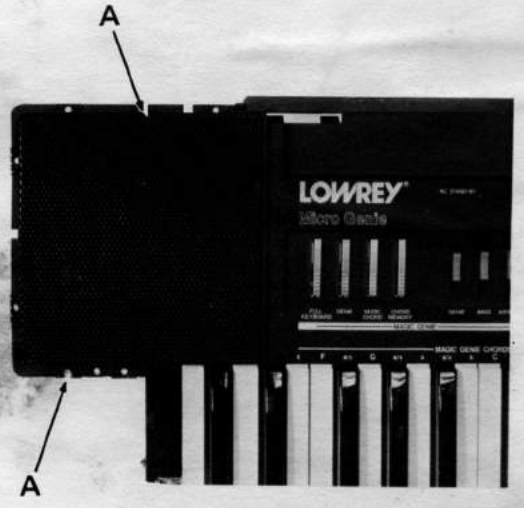


Endblock Disassembly

1. Remove base cover. (See Base Cover Removal.)
2. Remove 6 screws marked A. (Left endblock used as example.)
3. Disconnect cables.
4. Left endblock requires Q408 to be disconnected from keyboard chassis and right endblock requires ground wire to be disconnected from keyboard chassis.

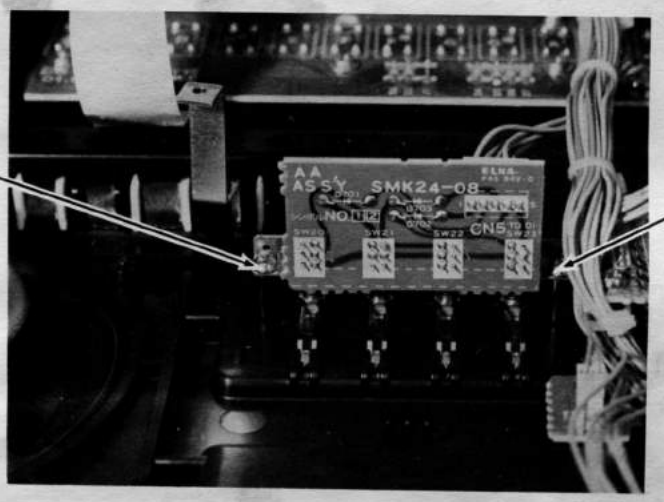
Speaker Grille Disassembly

1. Remove endblock. (See Endblock Disassembly.)
2. Remove 2 screws marked A.



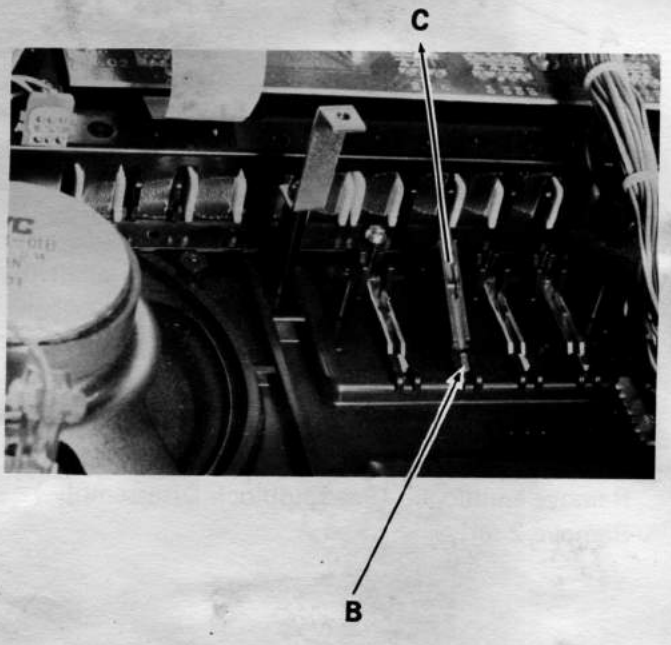
Speaker Removal

1. Remove endblock. (See Endblock Disassembly.)
2. Remove speaker grille. (See Speaker Grille Disassembly.)
3. Carefully remove grille cloth.
4. Remove 4 screws marked A.



Pushswitch Knob Replacement

1. Remove base cover. (See Base Cover Removal.)
2. Place board panel into service position. (See Board Panel Disassembly.)
3. Remove 2 screws marked A. (Board 6 used as example.)
4. Slide switch assembly toward keys and at same time lift upward.
5. Lift knob at point marked B and slide in direction of point marked C.



Potentiometer Knob Replacement

1. Place cloth on panel as illustrated.
2. Insert screwdriver in groove and remove knob by lifting up.

PARTS ORDERING PROCEDURE

Call: (800) 323-3532. In Illinois dial 312-759-5104. The toll-free number is available 24 hours a day, 7 days a week. During working hours, it is answered by Parts Department personnel.

or

Write: LOWREY SERVICE PARTS DEPARTMENT
1300 Naperville Drive
Romeoville, IL 60441

In Canada Call: (416) 752-5020

or

Write: LOWREY ORGAN COMPANY
A Division of Norlin Industries Ltd.
7 Credit Union Drive
Toronto, Ontario, Canada M4A 2S6

Be sure to include the following information:

1. Your name and address
2. Your account number
3. Shipping preference
4. Complete Part Number
5. A brief description of the part

If you wish to have the parts billed to one address and shipped to another, it is necessary to have the full name, address and account number of the store being billed.

If unknown and not in the service manual, provide a complete description of the part.

AVOID DELAYS BY USING COMPLETE PART NUMBERS

THE PARTS LIST CONTAINS THE FOLLOWING INFORMATION:

1. Name of Part
2. Value, Tolerance and Code (When Important)
3. Brief description
4. Where the part is found (assembly, printed circuit board, etc.)
5. Schematic Reference Number
6. PART NUMBER — USE IT!

This parts list includes all standard stock replacement parts. No attempt has been made to include every nut, bolt and screw. If the necessity for a non-listed part arises, please write describing the parts location and function as well as model and serial number of the unit.
